Title

Funding female entrepreneurs in MENA countries (2013-2019):
self-selection and discrimination

***Funding Female Entrepreneurs in MENA Countries (2013-2019):
Self-selection and Discrimination***

Imène Berguiga¹ and Philippe Adair²

Abstract: Do female entrepreneurs in MENA countries face obstacles in funding their business, either self-selection or discrimination? Literature review displays controversial evidence thereof and, so far, no paper tackled this funding issue for female entrepreneurs in MENA countries from a dynamic perspective. Three pooled samples from the 2013 and 2019 World Bank Enterprise Survey (WBES), and a cohort over 2013-2020, include three North African countries (Egypt, Morocco and Tunisia) and three Middle East countries (Jordan, Lebanon and Palestine); they document the financial behaviour of both owners and managers according to gender. Probit regressions address loan demand (including Heckman probit) and loan supply with respect to self-selection versus discrimination. There is neither self-selection nor discrimination for female entrepreneurs in 2013, whereas female entrepreneurs are prone to self-selection in 2019, as compared with their male counterparts. Self-selection behaviour from the demand side does not result from discrimination on the supply side. Sampling biases in the WBES together with the characteristics of female clients of microfinance institutions suggest that micro-entrepreneurs would have experienced self-selection and possibly discrimination regarding credit.

Keywords: Bank credit; Discrimination; Entrepreneurs; Gender; Heckit sample selection; Microfinance; Middle East and North Africa (MENA); Probit; Self-selection.

JEL Classification: D1; D8; D22; G2; G4.

Introduction.

The case of Middle East and North Africa (MENA) region is especially interesting, because the pervasive patriarchal pattern hinders the ability of women to own and manage their own businesses (IMAGES, 2017). Noteworthy is that gender gap for access to finance is 18 per cent in North Africa as of 2017, standing as the highest gap worldwide (Demirguc-Kunt et al., 2018). The lack of access to funding from formal financial institutions is one of the major problems confronting women entrepreneurs in MENA countries (AFEM, 2015; ILO, 2016; OIT, 2016). We tackle the finance issue for female entrepreneurs in six MENA countries, a set of resource-poor/labour abundant economies (Gatti et al., 2014), namely three North African countries (Egypt, Morocco and Tunisia) and three Middle East countries (Jordan, Lebanon and Palestine). We state our research question as follows: Do female entrepreneurs resist borrowing from banks because of their risk aversion? Are female entrepreneurs credit constrained due to discrimination from providers? To what extent self-selection and discrimination are independent and change over time?

In this respect, we investigate three pooled samples including the six MENA countries, which are issued from World Bank Enterprise Survey (WBES), respectively two panels as of 2013 and 2019/2020, as well as a cohort from the 2013 panel that is encapsulated in the 2019/2020 panel.

There is little empirical investigation on the topic of female entrepreneurship and no paper so far addressed the funding issue as of these six MENA countries from a dynamic perspective, to our best knowledge. Hence, our paper provides some new insights.

Section 1 reviews the literature devoted to self-selection and discrimination; there is little evidence regarding female entrepreneurs and outcomes from the loan funding gender issue proves controversial. Section 2 points out the advantages and setbacks of the WBES samples as for the six MENA countries; it presents the variables and descriptive statistics. Section 3 is devoted to model design and estimations from models applied to self-selection (probit and Heckman probit) as regards loan demand and models applied to discrimination (probit) with respect to loan supply. Section 4 overcomes WBES selection biases with the inclusion of the microfinance industry, which provides small amount loans to female microenterprises in the six MENA countries.

1. Literature review

The literature review on female entrepreneurs in the MENA region is sparse (Bastian et al., 2018) especially regarding comparative analyses.

1.1. Self-selection from the borrowing demand-side

Female entrepreneurs are supposedly more prone to risk aversion than men are (Watson, 2012), an inhibition resulting from fear of failure (Poggesi et al., 2016). However, the female risk aversion hypothesis proves controversial. There is scant literature besides game experiments, real-life situations remaining little investigated-

Among MENA countries, the North Africa sub-region is analysed by Morsy et al. (2019) upon a sample of 6,097 registered firms employing at least five employees from several distorted WBES datasets (Egypt, Mauritania, Morocco and Tunisia) in 2013 and before. A multinomial logistic regression rules out self-selection in response to discriminatory lending, and finds no evidence of gender discrimination. However, an instrumented probit model highlights self-selection, combining low perceived creditworthiness and female risk aversion.

Berguiga & Adair (2021) draw a pooled sample of 3,896 businesses in Egypt, Morocco and Tunisia from the 2013 World Bank Enterprise Survey (WBES), pointing out sample biases and including microenterprises that Morsy et al. (2019) overlooked. Four out of five managers are owners, whereas a relevant distinction between these two sub-categories applies to the remaining share of non-owners managers, a distinction that Morsy et al. (2019) do not document. Main results of two multinomial-logistic regressions upon loan demand and loan granting, with respect to self-selection vs. discrimination, show there is neither self-selection nor discrimination for female owners, whereas self-selection affects female managers.

1.2. Discrimination from the lender's supply side.

Two theories address discrimination. According to Becker (1957), taste-based discrimination is due to a prejudice towards one group of applicants based on gender and other personal characteristics. Phelps (1972) grounds statistical discrimination upon information asymmetry. Applying these theories to the credit market, lenders reject some loan applicants based on some observed characteristics such as gender, which are supposed to predict their creditworthiness. Evidence proves controversial. Hereafter, we contend that there is no gender discrimination if banks require women to have a bank account and provide a collateral exactly as they require similar lending conditions from men. Discrimination occurs if female entrepreneurs with the same characteristics as their male counterparts are denied a loan when they apply for it.

On the one hand, no discrimination affects female business owners/managers according to an experiment upon micro-enterprises female owners in Sri Lanka (De Mel et al., 2009).

Female entrepreneurs from SMEs are slightly less likely to be credit constrained in India (Wellalage & Locke, 2017). According to firm data from 16 sub-Saharan Africa countries, that female manufacturing entrepreneurs enjoy favouritism (positive discrimination) as for micro

and small firms, compared with their male counterparts, whereas the advantage is reversed for medium-sized firms (Hansen & Rand, 2014).

Bardasi et al. (2011) analyse a sample of more than 20,000 firms from 61 developing countries (Central and Eastern Europe, Latin America and sub-Saharan Africa), based on World Bank surveys from 2005 to 2007. The sample is corrected for endogeneity bias, but not for other selection biases affecting these surveys. A multinomial logit model addresses the following situations: a) businesses do not need a loan, b) need a loan but do not apply for it, c) need a loan and apply for it; in the latter case, either the loan application is approved, or it is dismissed. There is no gender discrimination in access to formal funding.

On the other hand, discrimination occurs for female business owners/managers

Muravyev et al. (2009) contend that discrimination on the credit market takes place across both Western and Eastern European firms, wherein female entrepreneurs face higher interest rate or higher requested collateral compared to their male counterparts.

Presbitero et al. (2014) use a Fairlie nonlinear decomposition model to test the presence of a gender gap as for access to finance in three Caribbean countries. The outcomes are that female entrepreneurs are less likely than other comparable firms to be discouraged borrowers, but they are more likely to be credit rationed.

From an institutional perspective, the question arises as to whether legislation prohibits gender discrimination in access to credit (Hyland et al., 2020). There is no prohibition in six MENA countries (World Bank, 2021). Barriers to Women Entrepreneurship Index displays varied scores (See Table A in the Appendix).

Gender stereotypes are pervasive in a 2016 survey upon nearly 10,000 people aged 18-59 from Egypt, Lebanon, Morocco and Palestine. Most men believe that women are not fit to manage, should not work outside their home, and that educating boys is more important than educating girls (IMAGES, 2017).

Amara et al. (2018) applying logistic regression and propensity score matching upon a cross-section sample of 9,382 individuals, find that female entrepreneurs experience significant gender discrimination in Tunisia.

A non-representative sample of 583 female entrepreneurs was collected by women associations in six MENA countries: Egypt, Jordan, Lebanon, Morocco, Palestine and Tunisia (Carco et al., 2017). Female entrepreneurs, aged 40 on average, are mostly university graduates and enjoy 10 years of experience in their family-based businesses that operates in the services, trade and craft, rather than in the manufacturing industries. The share of non-registered businesses is over one third in Egypt, whereas it is only four to 10 per cent in Morocco and Tunisia. The gap to

access financing for females compared with their male counterparts is lowest in Egypt and Tunisia, being highest in Morocco and Palestine.

2. Pitfalls and advantages of the WBES data source, variables and descriptive statistics

2.1. Pitfalls and advantages of the WBES data source

The WBES samples include three biases, which question their representativeness: the sample size by country, the very small share of unregistered enterprises and the overrepresentation of medium and large enterprises as well as of the manufacturing industry. Concerning the weight of countries, Egypt is overrepresented (53.02%) and Morocco (7.45%) is very underrepresented in the 2013 panel, whereas the 2019/2020 panel is larger and more balanced with respect to population size: North Africa accounting for about three-quarters (76.16%) of enterprises and the Middle East about a quarter (23.83%). North Africa (56.11% of enterprises) and particularly Morocco (10.27%) are under-represented in the 2013-2020 cohort. The almost complete absence of unregistered enterprises (plus or minus 1%) is unrealistic. Last, medium and large enterprises amount around 30%, though these categories account far less than 10 per cent of all MENA enterprises (Ayadi and Sessa, 2017), whereas the manufacturing industry includes a disproportionately large share (over half the firms).

However, WBES has two main advantages. On the one hand, the coverage of the private sector is consistent, excluding agriculture, public utilities, government services, health care and financial services industries. On the other hand, the harmonised questionnaire collects a large spectrum of data through face-to-face interviews with firm managers and owners. A large set of 26 questions thoroughly investigate the finance topics and overall information on loan application by businesses during the survey period is available.

2.2. Samples, variables and descriptive statistics

First of all, we compare the three pooled samples, respectively the 2013 panel (5,464 companies) and the 2019/2020 panel (6,284 companies), as well as the 2013-2019/2020 cohort (1,353 companies). Thus, we can track variables that change from one panel to another or remain constant over time (See Table A2 in the Appendix⁵).

Noteworthy is that a few variables are constant by construction in the 2013-2020 cohort. This is the case with the weight of enterprises by country, as well as the *education of the manager*. Conversely, the *Manager experience* together with the *Age* of enterprises increase in the cohort. In contrast, some characteristics of companies vary in the same direction, both in the panels as well as in the cohort. Such is the case for *Ownership*, with an increase of *Sole proprietorship*.

⁵ For the sake of parsimony, correlation matrices are omitted, but remain available on request.

whereas the weight of the *Manufacturing industry* together with the share of *Micro* and *Small* enterprises are rising in the panels and decline in the cohort.

In both panels and the cohort, most funding patterns are consistent: *Self-selection* rises, whereas *Loan application (demand)* and *Loan purpose (working capital and fixed assets)* drop together with *Loan granted (supply)* and requested *Collateral* increases; *Loan duration* is rising as for the panels and drops in the cohort.

As for the *Owner gender* and *Manager gender*, directions are different: the share of female *owners* declines in both the panels and the cohort, whereas the share of female *managers* is rising in the panels and decline in the cohort.

As regards the 2013 full sample, self-selection is negatively correlated with *Size*, *Age*, *Ownership*, *Financial inclusion* and *Loan purpose*, whereas it is positively correlated with *Personal loan* that is an alternative to bank credit. Discrimination is negatively correlated with *Size*, *Age*, *Financial inclusion* and *Sales Turnover*, all variables that prove consistent, while it is positively correlated with *Sub-region*.

With respect to the 2019 full sample, self-selection is negatively correlated with *Size*, *Gender management*, *Management experience*, *Financial inclusion*, *Sales Turnover*, *Inflation* and *GDP per capita*, whereby variables are consistent, whereas it is positively correlated with *Loan purpose*, *Personal loan* and *Sub-region*.

Discrimination is negatively correlated with *Size*, *Sales Turnover*, *Collateral* and *Inflation*.

As regards the 2013 cohort sample, self-selection is negatively correlated with *Size*, *Age*, *Ownership* and *Financial inclusion*, and it is positively correlated with *Personal loan* and *Inflation*. Discrimination is negatively correlated with *Loan purpose*.

With respect to the 2019 cohort sample, self-selection is negatively correlated with *Gender ownership*, and it is positively correlated with *Personal loan*. Discrimination is negatively correlated with *Financial inclusion*.

3. Probit regressions: Self-selection and discrimination

3.1. Model design

Our model is a sequential choice model, which can be best designed with a decision tree including three binary options: (i) no funding need vs. funding need prior to (ii) no loan application (self-selection) vs. loan application and (iii) loan denied (potential discrimination) vs. loan granted (See Box 1 and Figure A1 in the appendix). Noteworthy is that the final choice does not belong to the companies on the demand side, but to the banks on the supply side. Hence, a nested logistic regression is not an appropriate method. Instead, we use a probit and a Heckman probit for sample selection correction.

Box 1. Probit model

Both models apply to the pooled sample including every business i located in country $k = [1$ (Egypt), 2 (Jordan), 3 (Lebanon), 4 (Morocco), 5 (Palestine) and 6 (Tunisia)].

The model for loan demand is binary and self-selection comes from the absence of application (=0) as follows:

$$\mathbf{Self - selection}_{ik} = \begin{cases} 1 & \text{if credit was not needed and not applied for in 2013 and 2019 - 2020} \\ 0 & \text{if credit was needed but not applied for in 2013 and 2019 - 2020} \end{cases}$$

The model for funding supply is binary and discrimination comes from the denial of application (=0) as follows:

$$\mathbf{Discrimination}_{ik} = \begin{cases} 1 & \text{if credit was applied for and was granted b in 2013 and 2019 - 2020} \\ 0 & \text{if credit was applied for but was denied * in 2013 and 2019 - 2020} \end{cases}$$

* Discrimination is conditional to the comparison between female and male entrepreneurs.

Both models are estimated according to the general equation for the explained variable Y :

$$E(Y = 1/X_{ikj}) = P_{ikj} = \sum_j \alpha_j X_{ikj} + \sum_j \beta_j V_{ikj} + \sum_j \delta_j W_{ikj} + \sum_j \varphi_j Z_{ikj} + \sum_j \gamma_j S_{jk} + \varepsilon_j$$

Wherein explanatory variables are the following: X_j = characteristics of the companies; W_j = financing need; Z_j = characteristics of the loan; S_{jk} = macroeconomic indicators (control variables), and ε_j is the error term..

3.2. Self-selection

Our self-selection model is determined by the following explanatory variables: Characteristics of the business (*Size; Industry; Age; Ownership and Gender*) and financial characteristics (*Personal loans; Sales Turnover and Financial inclusion*) plus a control variable (*Sub region*).

We use two estimation methods: a probit and a Heckman probit. Heckman probit takes care of selection issues in our samples and checks the robustness of the results obtained with the probit. Such selection issues are the following: our samples are non-random, a specific type of endogeneity; there are attrition biases due to missing (and truncated) data in the questionnaire; the explanatory variable may be endogenous rather than exogenous; unobservable variables could have an impact on the explanatory variable (Gender) and the explained variable (self-selection), among which there is risk aversion.

Heckman probit is a two-step model. In the first equation, the company decides whether it has not (=0) or it has a financing need (=1), in the second equation, provided there is a prior need for funding, it decides whether to self-select (=0) or apply for credit (=1). The explanatory variables of two equations are the same, only the *loan purpose* variable is added in the second equation.

Both probit and Heckman probit apply to every sample and for each gender variable: *Gender ownership* and *Gender manager*. According to estimation results as of year 2013, female owners are less self-selecting than males (Table 1), whereas there is no relationship between gender and self-selecting behaviour in 2019 (Table 2).

To monitor the robustness of our results, we tackle the evolution of this behaviour over time, estimating the same sample of companies observed in both 2013 and 2019. Results for 2013 confirm that female-owned businesses are less self-selecting in 2013. However, their behaviour changed in 2019, these companies are now self-selecting. The question arises: Is this change due to discrimination that occurred in 2013? Could self-selection behaviour in 2019 be explained by the decision of financial institutions to deny credit in 2013 and does rejection vary according to gender?

On the demand side, the issue is to discern whether the probability of companies self-selecting in 2019 depends on credit denial they may have faced on the supply side in 2013; hence, this last variable was included in the self-selection model. However, Table 3 reports that the Wald test of both probits displays a probability beyond 10 per cent and variables prove non-significant. This allows us to conclude that self-selection in 2019 is independent from discrimination in 2013; leaving room enough for other (unobservable) factors that would explain this change in behaviour, including attrition issues.

Actually, this result was expected; cross-sorting variables of self-selection in 2019 with discrimination in 2013 shows that, out of 145 companies, only three companies that were discriminated against in 2013 did self-select in 2019.

Table 1. Estimation of the self-selection model, 2013 and 2019

3.3. Discrimination

On the supply side, the decision to deny (=0) or to grant a loan (=1) is no longer into the hands of the companies but belong to the financial institutions. In as much as decision is exogenous, a Heckman probit proves useless. We design a probit model measuring the probability of rejecting or accepting credit application from companies, including the following explanatory variables: characteristics of the business (*Size, Industry, Age and Ownership*), the requirements of financial institutions (*Collateral and Financial inclusion, Loan purpose and Turnover*) and Control variables (*GNI per capita and Inflation*).

In order to infer whether there is gender discrimination from financial institutions as for credit granting decision, we include *Gender ownership* and *Gender manager* in interaction with *Collateral* and *Financial inclusion*.

This model is estimated in 2013 and again in 2019. Table 4 records estimation results showing that interacting variables are significant and signs remains constant over time for female as for male owners or managers. Gender discrimination on the part of financial institutions does not occur in loan granting decisions as of both 2013 and 2019. Noteworthy is that, only the financial inclusion variable that interacts with the gender of managers is significant for both males and females in 2019; hence, financial inclusion runs opposite to rejection probabilities.

Table 4. Probit estimation of loan rejection in 2013 and 2019

Note: Robust z-statistics in parentheses *** p<0.01, ** p<0.05, * p<0.1

The estimation of this model on the cohort observed in 2013 and 2019 does not confirm the absence of discrimination, on the one hand, and points out a change in credit granting decisions by financial institutions, on the other hand. Indeed, the probabilities of Wald test stand over 10 per cent and some variables are omitted, which is due to the very low number of companies that have been denied credit.

4. Enlarging the picture: the informal sector and funding from the microfinance industry

Aforementioned results from WBES suggesting the absence of discrimination and some self-selection for female managers prove inconsistent with several more qualitative surveys, though based upon smaller samples. Over a quarter of the businesses among 400 female entrepreneurs in Morocco (AFEM, 2015) faced difficult access to finance. Less than one out of six among 200 female micro-entrepreneurs in Egypt (ILO, 2016) applied for a loan but less than half was granted, female business owners claiming that lending conditions were too restrictive and interest rates too high. Access to finance was the major obstacle as for seven out of ten businesses in a sample of 201 female entrepreneurs in Tunisia (OIT, 2016).

Banks loans do bear an interest rate and require a collateral and the share of loans increases with the size of businesses (Rocha et al., 2011), whereas loans from Microfinance Institutions (MFIs) charge an interest rate but do not usually require a collateral and fund especially micro-enterprises.

Microenterprises prove underrepresented in the WBES and this is a serious bias for several reasons. First, because these businesses are the most widespread and more prone to be informal, the self-employed and micro-enterprises account for more than 50 per cent of employment in the manufacturing industry, and informal employment accounts for more than 60 per cent of overall employment (ILO, 2019). Second, they are facing the most difficult access to finance (Kushnir et al., 2010) and they include a significant share of female entrepreneurs (ILO, 2018). The WBES overlooks the role of microfinance that is included in Non-Banking Financial Institutions, a puzzling result in as much as the *raison d'être* of the microfinance industry is to provide funding to Micro and Small enterprises, most of which are informal, being not registered with a national government authority and without bookkeeping (ILO, 2013). For instance, almost one out of six informal micro-enterprises in Morocco enjoyed a microcredit, whereas one out of 20 was granted a bank loan (HCP, 2016).

Hence, funding from the microfinance industry displays a better picture than that of WBES.

Table 5 reports the key figures of the microfinance industry, namely 20 MENA MicroFinance Institutions (henceforth MFIs) with the most complete client data as of year 2017 from the MIX database (year 2018 is not completed yet). Among active borrowers (NAB), three out of five are females and over nine out of ten are MSMEs. In the first place, MFIs grant micro-credit to *Micro*-enterprises, a share above eight out of ten, whereas SMEs is only one out of ten. Over two out of five businesses are granted loans according to the joint liability mechanism, suggesting they lack collateral. Average loan balance per borrower in MENA is weak, with the exception of Palestine standing above average. In contrast, the average lending rate is high,

within a range of 25-36 percent, although borrowers payback. In this respect, MSMEs can afford funding working capital rather than fixed assets.

Agier & Szafarz (2013) do not detect discrimination in female access to credit from a Brazilian MFI. However, they observe that largest female projects face the highest penalty, thereby confirming that microcredit is not the best vehicle for funding capital investment. These results are consistent with observations from MENA MFIs, as well as from micro-enterprises in Morocco (HCP, 2016). We assume that female active borrowers from MENA MFIs were either self-selecting and/or discriminated by formal finance vs. they prefer microfinance. Such assumptions are worth a test that goes beyond the scope of this paper.

Table 5. MFIs in the selected MENA countries (2017)

Discussion and conclusions

Self-selection and discrimination affecting female entrepreneurs in the MENA region are controversial issues, upon which our paper brings in new insights. In particular, it proves inconsistent with Morsy et al. (2019) as regards self-selection and discrimination, as well as with Berguiga & Adair (2021) with respect to discrimination, both papers investigating prior WBES devoted to MENA countries.

We designed a sequential choice model with a decision tree whereby two main binary options are relevant: provided that companies need funding, their option on the demand side is no loan application (self-selection) vs. loan application. The final option does not belong to the companies on the demand side, but to the banks on the supply side; it is loan denied (potential discrimination) vs. loan granted.

On the demand side, we use both a probit and a Heckman probit for sample selection correction, whereas a probit is appropriate to tackle the supply side.

According to estimation results as of year 2013, female owners are less self-selecting than males, whereas there is no link between self-selecting behaviour and gender in 2019.

We address the self-selection behaviour over time upon the 2013-2019 cohort. Estimation results confirm that female-owned businesses are less self-selecting in 2013. However, their behaviour changed in 2019, these companies are now self-selecting. Including discrimination as for 2013 in the self-selection model applied to 2019 shows that that self-selection in 2019 is independent from discrimination in 2013.

Gender discrimination on the part of financial institutions does not occur in loan granting decisions as of both 2013 and 2019.

However, all studies on the MENA region that use WBES encapsulate several biases regarding in particular the size of businesses, which make funding look like a fairy tale. The fact that the microfinance industry provides credit to female microentrepreneurs suggest another story about self-selection and perhaps discrimination, which do occur for these businesses.

Among some limitations of the paper that pave the way for future research on self-selection and discrimination in MENA countries, two are worth mentioning: Investigating the reasons why a shift in behaviour took place over 2013-2019, exploring the characteristics of (female) entrepreneurs who are granted a loan from the microfinance industry.
